Introduction to Clinical Cytogenetics

1/23/03

Joan H.M. Knoll, Ph.D., FACMG, FCCMG
Children's Mercy Hospital
School of Medicine
University of Missouri-Kansas City

What is Cytogenetics?

- study of chromosomes; for clinical cytogenetics, it is applying the study of chromosomes to clinical medicine (diagnosis - postnatal, prenatal, cancer; gene mapping)

What types of tissues can be used to study chromosomes?

- for routine chromosome analysis, cells must have a nucleus, be viable at time of collection and capable of undergoing cell division (cells are grown in culture)

- for certain molecular cytogenetic applications, cell division is not a requirement

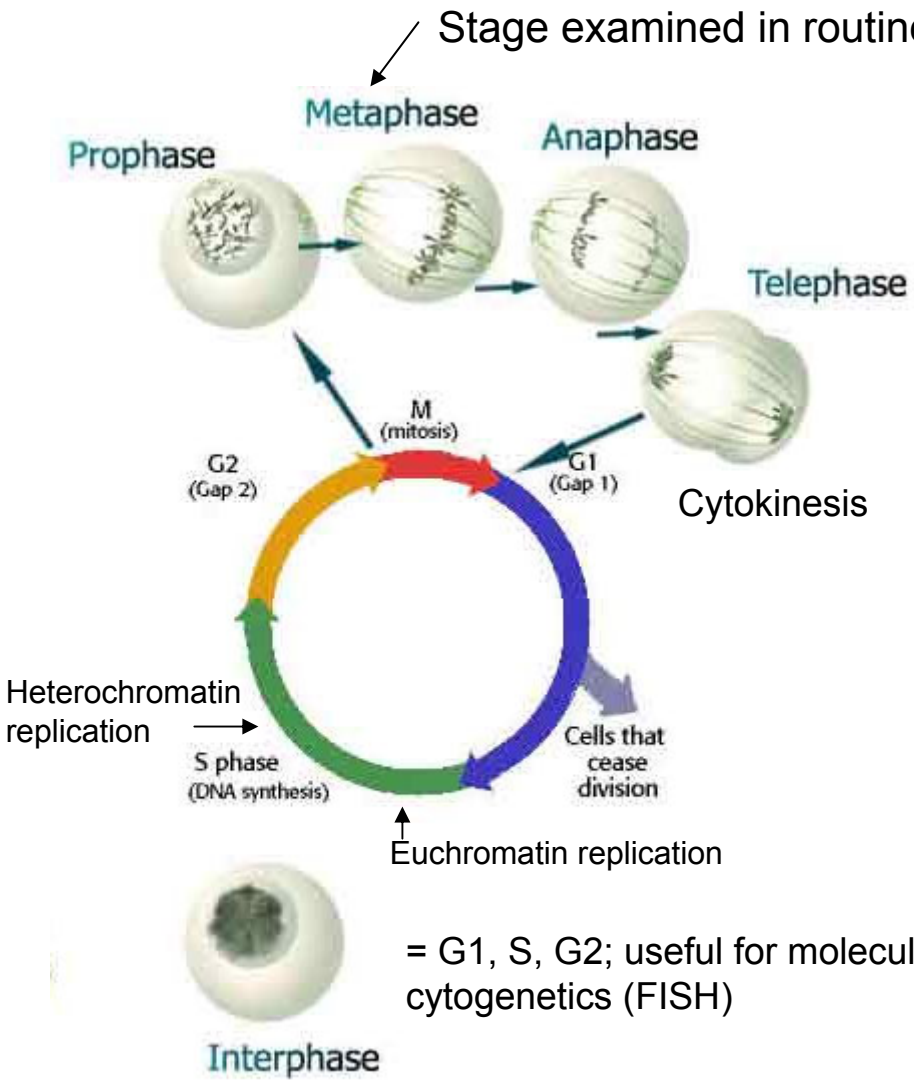
Why perform clinical cytogenetic testing?

- fertility problems – couples with history of infertility or habitual pregnancy loss; females with amenorrhea
- malformed fetus; stillbirths and neonatal deaths where a cytogenetic basis is likely
- pregnancy in women of advanced age
- family history in first degree relatives
- dysmorphology, problems of early growth and development (FTT, DD, Dysmorphic facies, MR, ambiguous genitalia, multiple malformations including cardiac anomalies
- Neoplasia (can be diagnostic or prognostic)

Frequency of Chromosome Abnormalities

- ½ to 1% of all live births
- 2% of recognized pregnancies in women > 35 y.o.
- 10% of stillbirths
- ½ of recognized spontaneous pregnancy losses
- high in neoplasias (type dependent)

Mitotic Cell Cycle:



= G1, S, G2; useful for molecular cytogenetics (FISH)

- G1- cell grows and performs normal metabolism; organelles duplicate (~10-12 hours)
- S – DNA replication and chromosome duplication (~6-8 hours)
- G2 – cell grows and prepares for mitosis (~2-4 hours)
- M – mitosis – chromosomes are maximally condensed (~ 1hour)
- transitions between phases mark crucial regulatory checkpoints and are often rate limiting

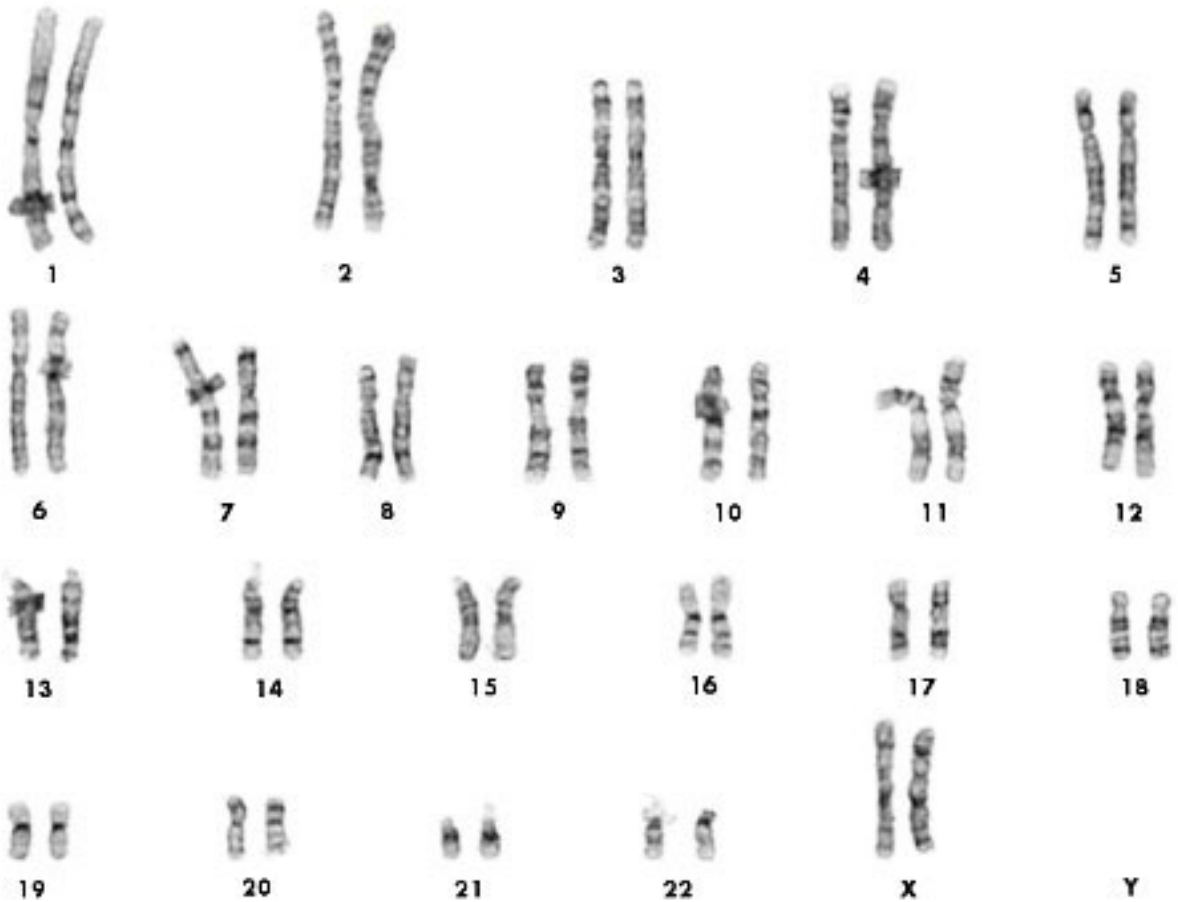
Normal Female karyotype

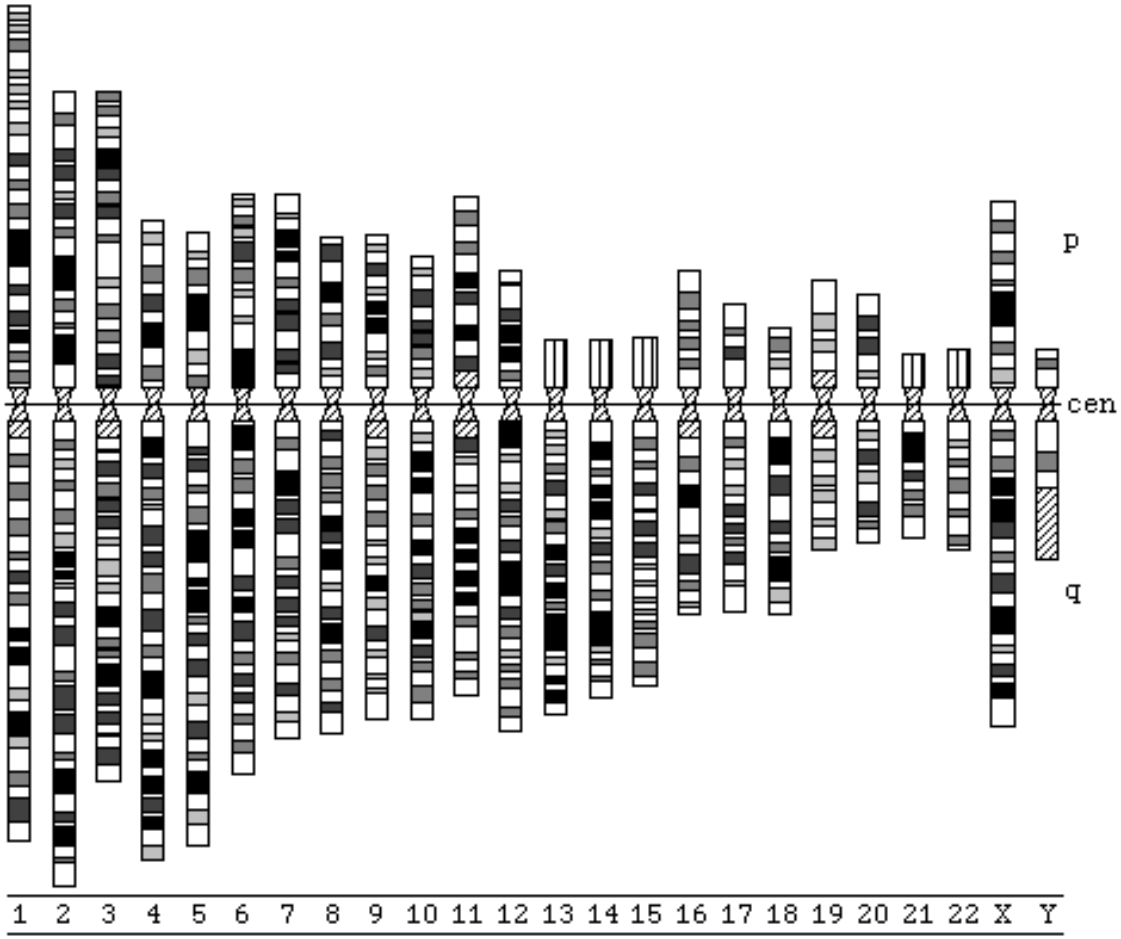


From Children's Mercy Hospital Cytogenetics Laboratory

Normal Male karyotype

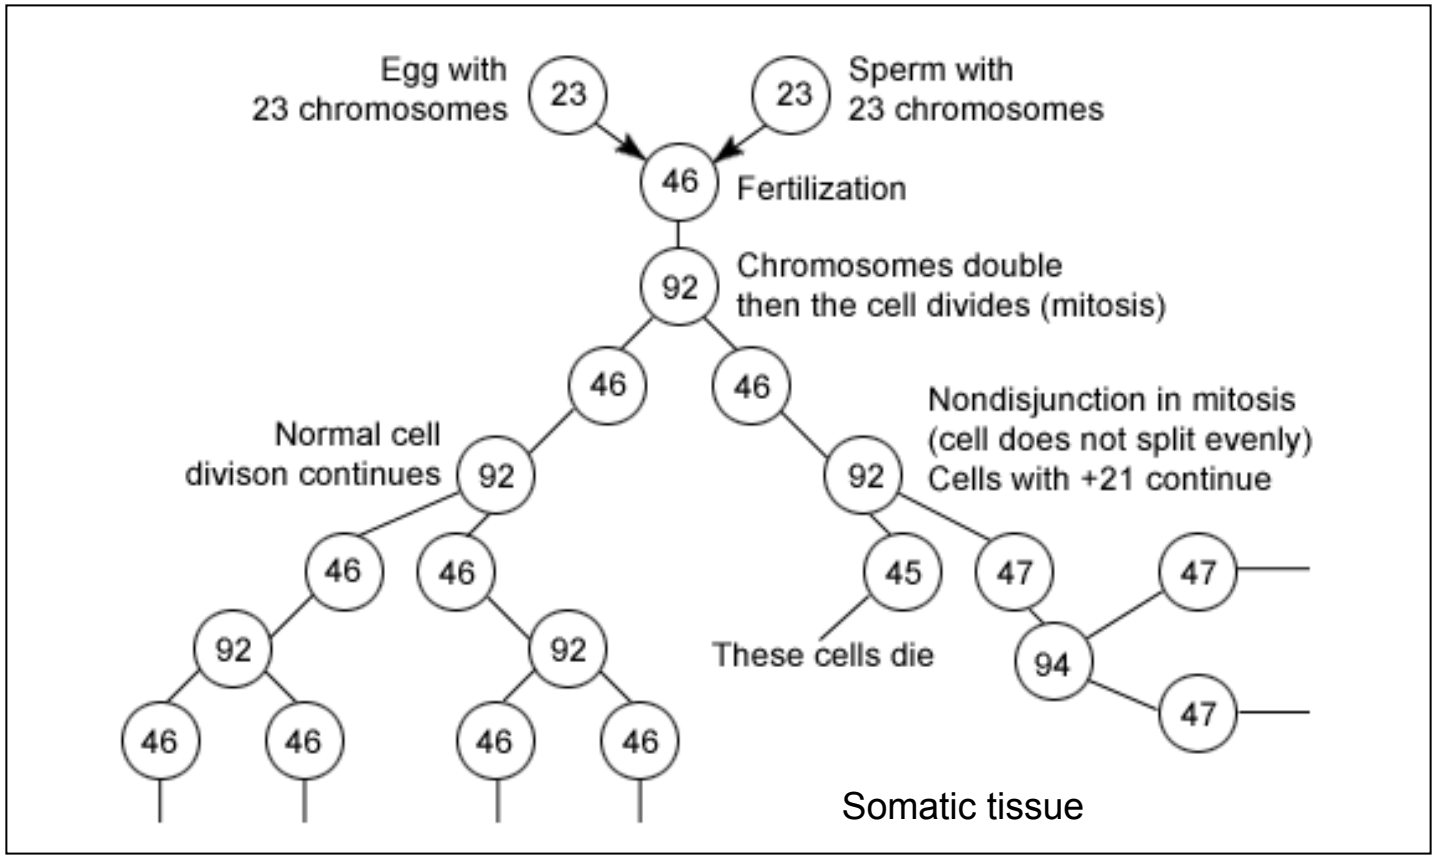
From Children's Mercy Hospital Cytogenetics Laboratory

Ideogram: Human Chromosomes



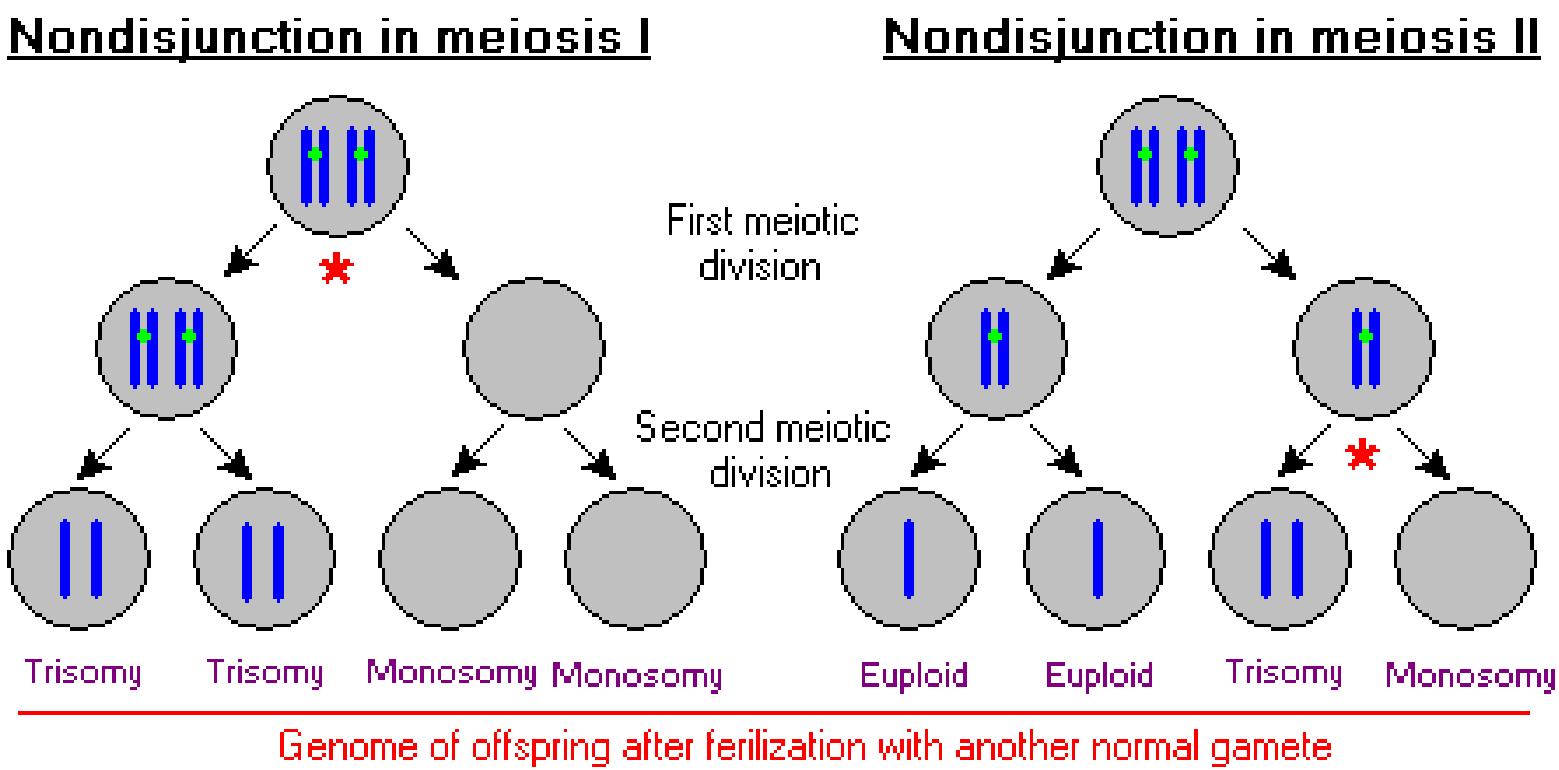
Chromosomal Mosaicism:

One or more cell lines in an individual derived from a single zygote



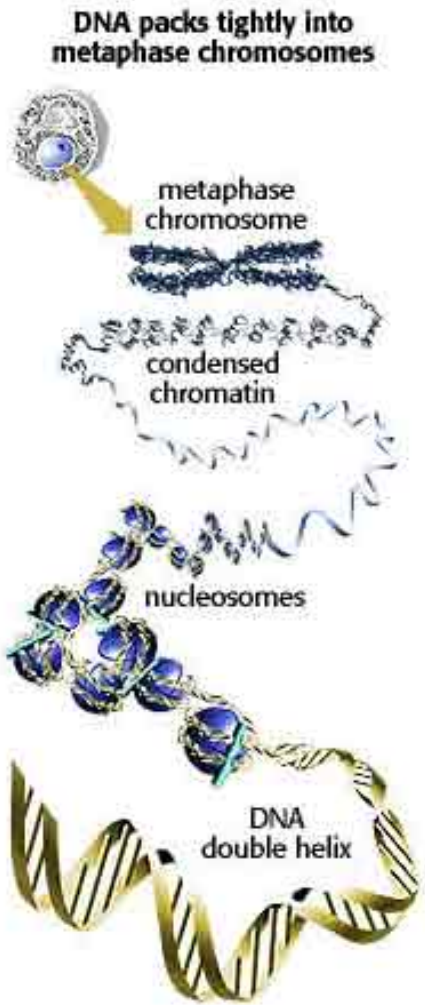
Eg. **47,XX,+21/46,XX or 47,XY,+21/46,XY**

Q: Does 46,XX/46,XY represent a mosaicism?



Nondisjunction in meiosis I
Nondisjunction in meiosis II
First meiotic division
Second meiotic division
Trisomy
Trisomy
Monosomy
Monosomy
Euploid
Euploid
Trisomy
Monosomy
Genome of offspring after ferilization with another normal gamete

Chromosome Structure:



- 3 billion nucleotides per human haploid genome (23 chromosomes)
- chromosome sizes range from 35 million (chrom 22) to ~180 million (chrom 1)
- >2 meters of DNA per diploid nucleus; >10,000 fold compaction
- cell needs to access information in timely and orderly manner
- human genome draft sequence published in Feb'02; completed sequence expected later this year

Telomere [TTAGGG]n -
Not chromosome specific; adjacent subtelomeric regions are chromosome specific
st = stalk; NOR; rRNA genes
sa = satellites

Nomenclature:

of chromosomes with centromeres**,** sex chromosomes**,** abnormalities listed by chromosome number from 1 through 22 and alphabetically by type of abnormality

Egs. 46,XY and 46,XX

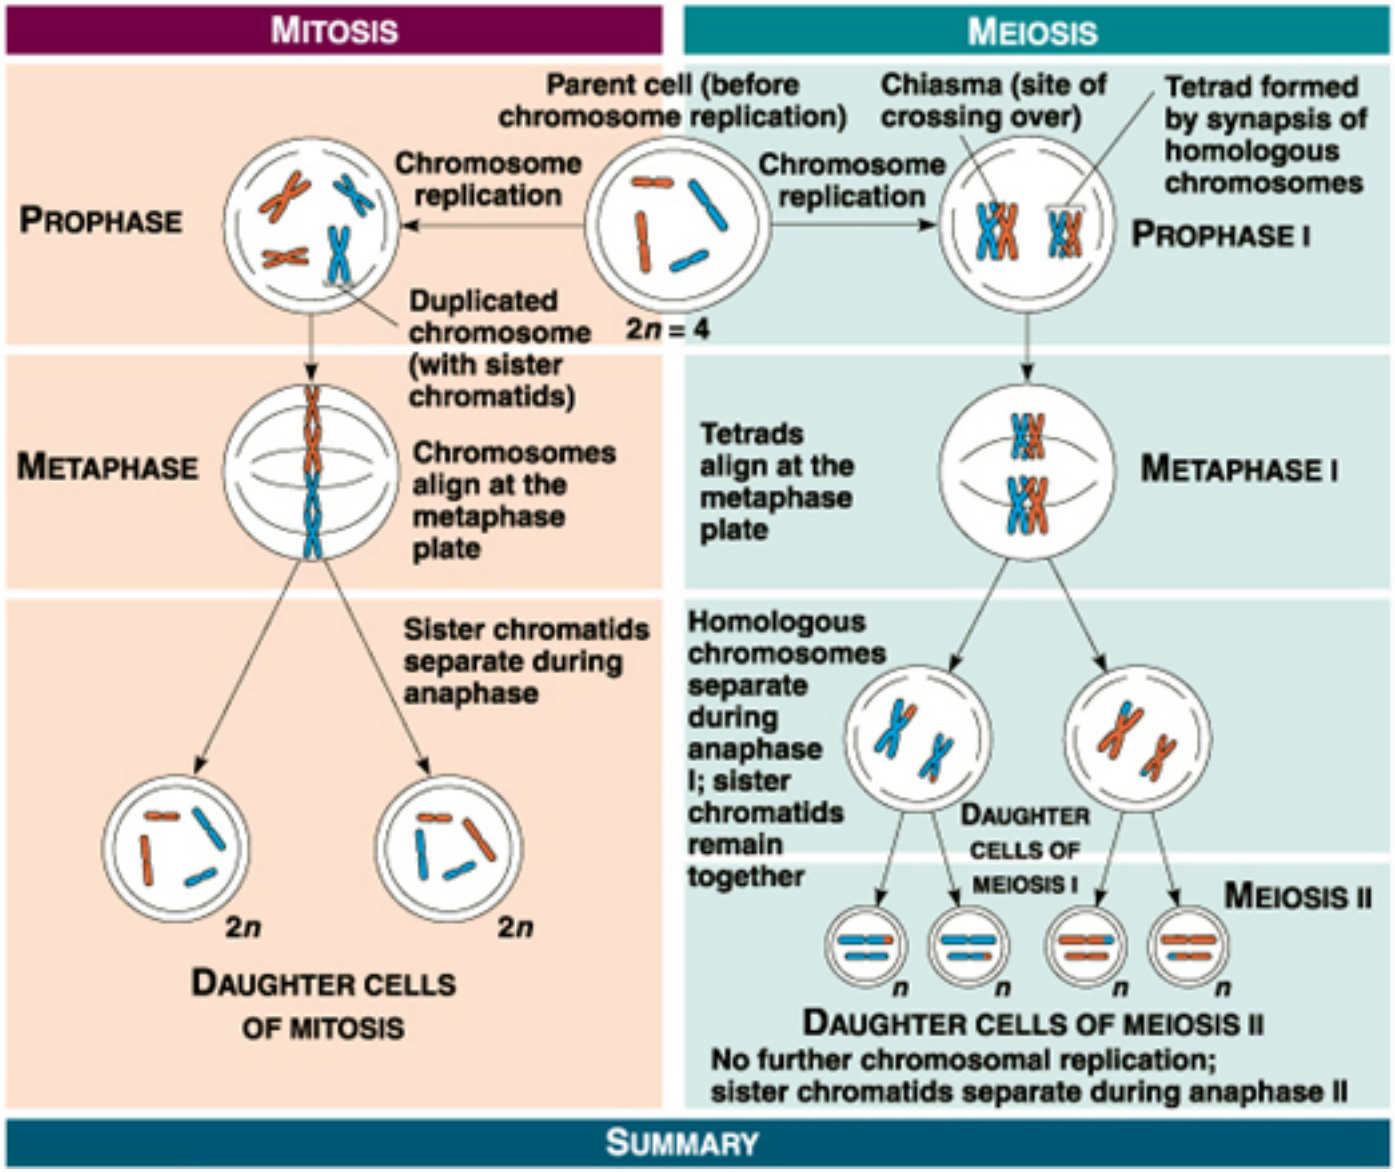
47,XXY and 47,XX,+21 and 45,X

46,XX,del(15)(q11.2q13)

45,XX,t(14;21)(q10;q10)

46,XY,t(14;21)(q10;q10),+21

47,XY,t(1;17)(p32;q12),inv(3)(p25),+4,add(6)(q21q23),del(6)(p25)



MITOSIS
MEIOSIS
Parent cell (before chromosome replication)
Chiasma (site of crossing over)
Tetrad formed by synapsis of homologous chromosomes
Chromosome replication
Chromosome replication
PROPHASE
PROPHASE I
Duplicated chromosome (with sister chromatids)
2n = 4
METAPHASE
Chromosomes align at the metaphase plate
Tetrads align at the metaphase plate
METAPHASE I
Sister chromatids separate during anaphase
Homologous chromosomes separate during anaphase I; sister chromatids remain together
DAUGHTER CELLS OF MEIOSIS I
MEIOSIS II
2n
2n
n
n
n
n
DAUGHTER CELLS OF MITOSIS
DAUGHTER CELLS OF MEIOSIS II
No further chromosomal replication; sister chromatids separate during anaphase II

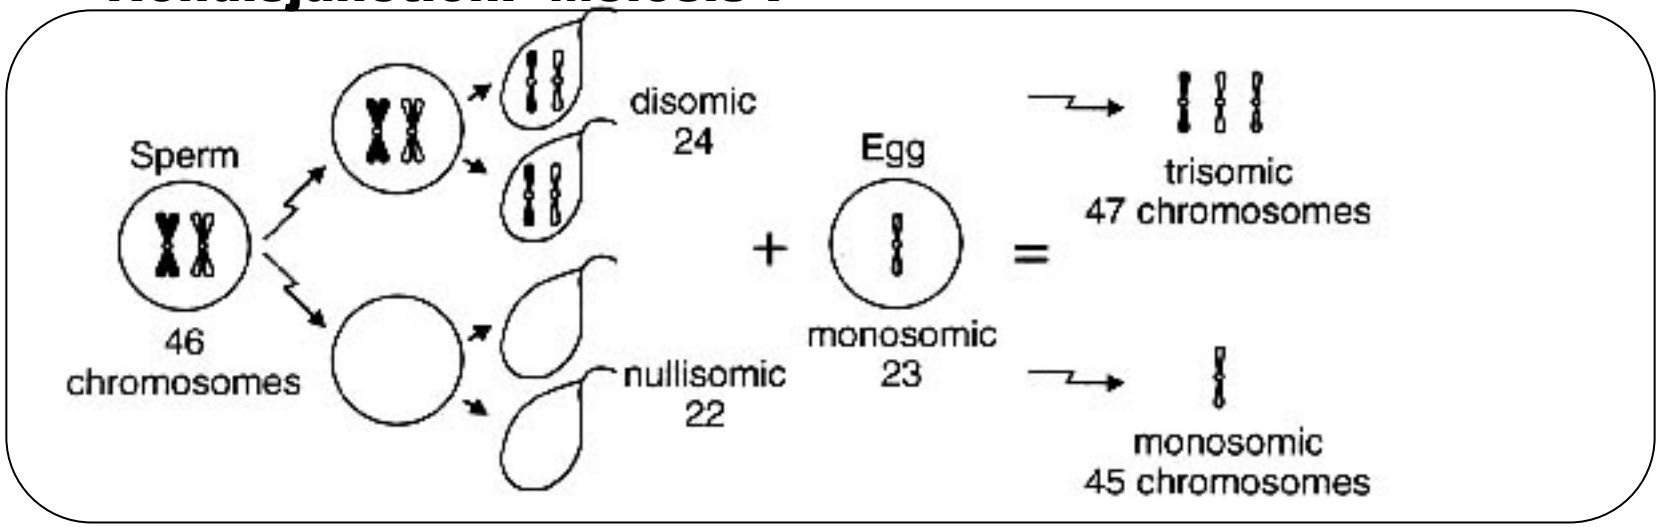
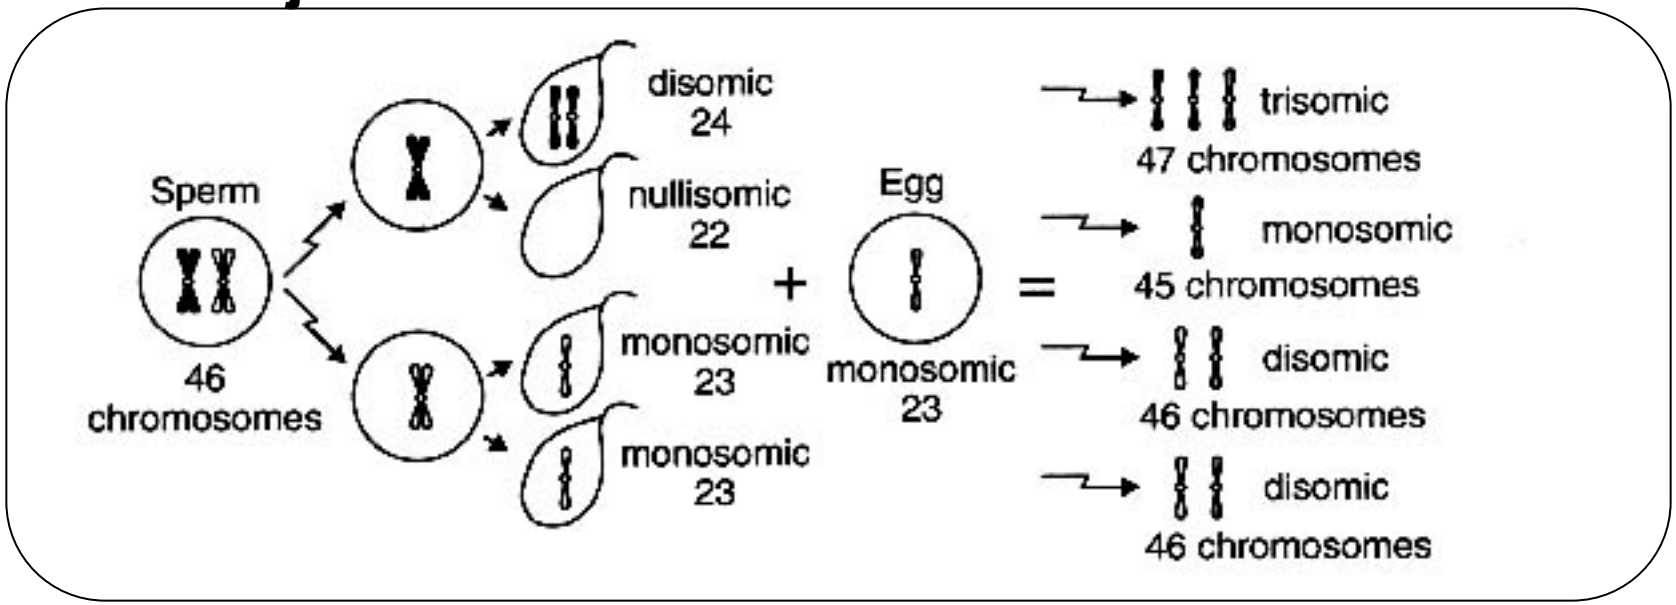
Nondisjunction: Meiosis I



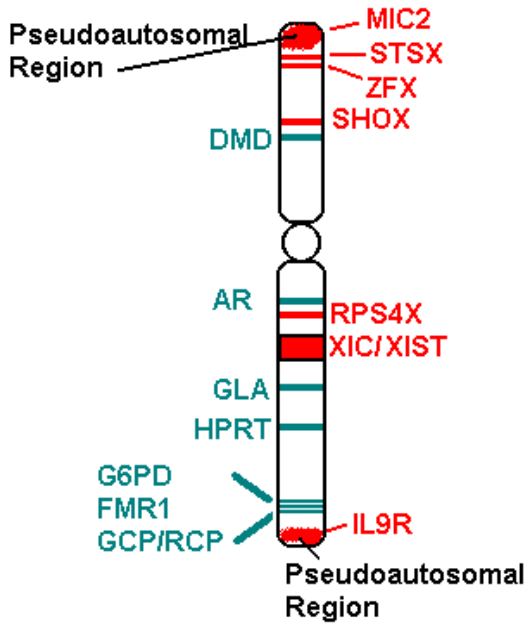
Nondisjunction: Meiosis II



Fertilization **Zygotes**

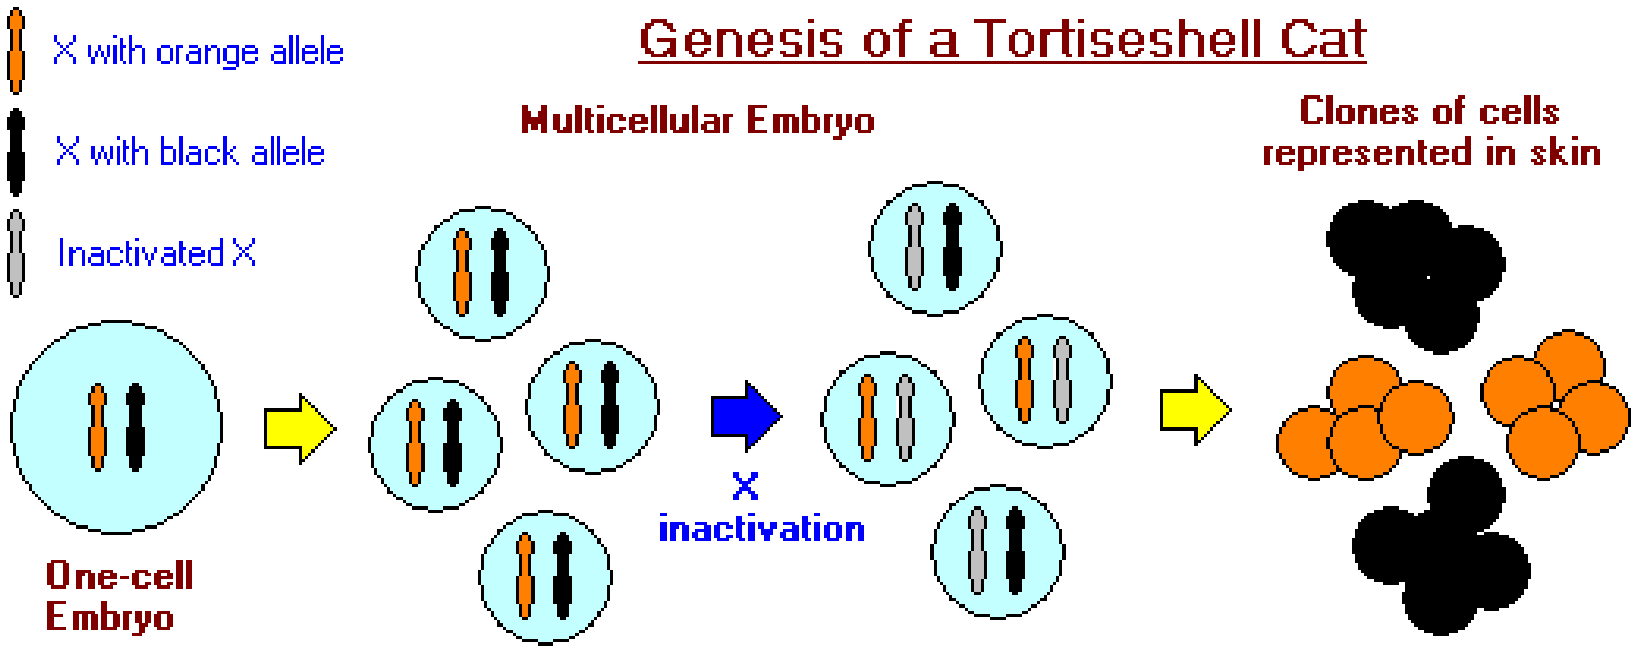
X-Inactivation or Lyonization:

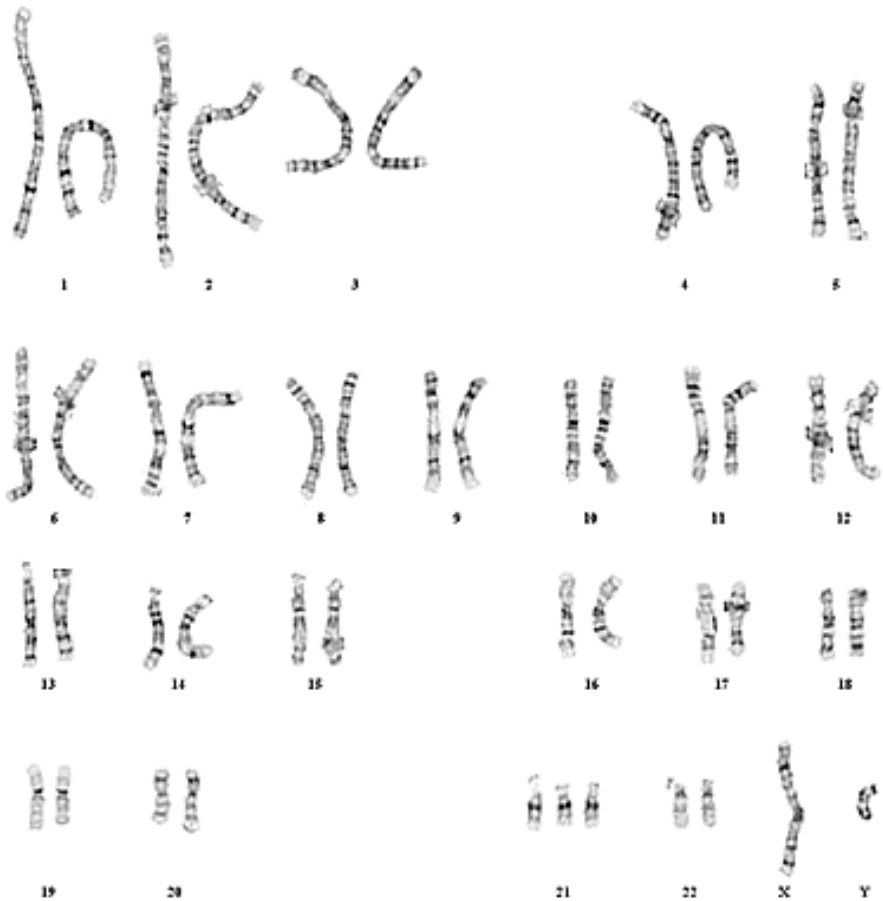
- form of gene dosage compensation between females (XX) and males (XY)
- generally occurs randomly in blastocyst (maternal or paternal)
    - if abnormal X involving t(X;autosome) then abnormal X remains active
    - if abnormal X involves deletion, duplication, etc then abnormal X is inactive
- permanent
- one active X per cell but inactive X does have some genes that remain active
- inactive X is late replicating, forms Barr body and is very compacted
- XIST gene (RNA) initates inactivation and is expressed from inactive X



Egs. of inactive (left) and active (right) genes on 'inactive' X.

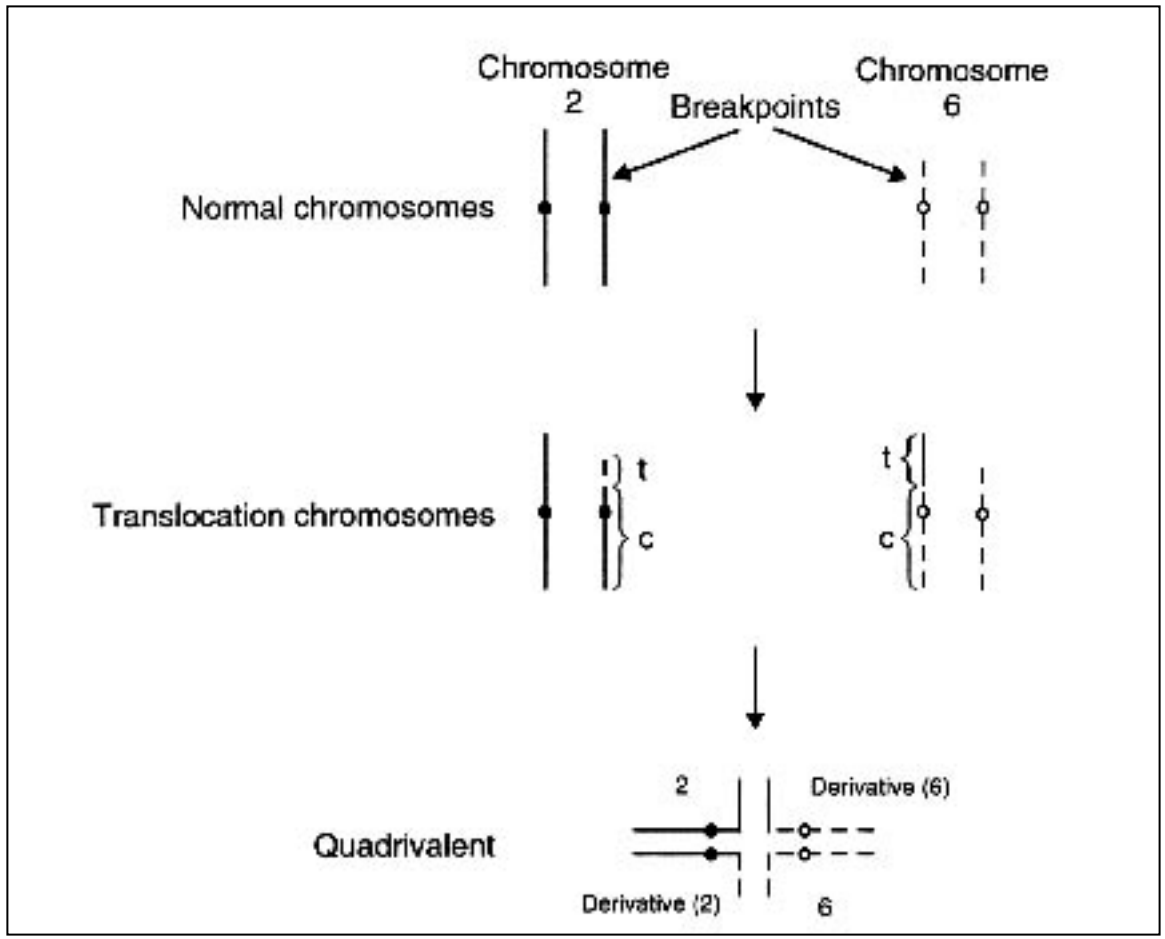
X-Inactivation or Lyonization





47,XY,+21

Meiotic Pairing of a Reciprocal Translocation



Possible Gametes: 2,6 and der(2),der(6) [Alternate segregation – balanced];
2,der(6) and der(2),6 [Adjacent 1 – unbalanced];
2,der(2) and der(6),6 [Adjacent 2 – unbalanced]
